VETERINARY TECHNICAL DATASHEET

Macrothrombocytopenia; disease-linked variant originally found in Norfolk and Cairn Terrier

W¥SDOM[™] HEALTH

Mutation Found In :Cairn Terrier, Norfolk Terrier

Disorder Type

• Blood

Disease Severity

• Mild

Background

Congenital macrothrombocytopenia is a blood disorder characterized by oversized platelets and a low platelet count. Platelets, also called thrombocytes, are produced in the bone marrow and play an important role in the blood clotting system when a blood vessel is injured. The original mutation was first identified in the Cavalier King Charles Spaniel and is known to cause macrothrombocytopenia in several other breeds as well. This particular mutation variant however has been identified in Norfolk Terriers and Cairn Terriers.

Key Signs

• Low platelet count

• Macroplatelets

Clinical Description

Next Steps

Congenital macrothrombocytopenia is characterized by oversized platelets, also called macroplatelets, and an abnormally low number of platelets. Macroplatelets function normally and the affected dogs do not exhibit any health problems due to either the size or the lower platelet count. Macrothrombocytopenia is not associated with spontaneous bleeding.

While this disorder is relatively mild, it is important not to mistake macrothrombocytopenia

for other more severe conditions characterized by low platelet counts.

Mode of Inheritance

autosomal recessive

Gene Name

• TUBBI
